13

14

1 **Summary**

2 So far, at least eight alleles in the goat CSN2 locus have been associated with the level of b-casein
3 expression in milk. Alleles CSN2 A, CSN2 A1, CSN2 B, CSN2 C, CSN2 D and CSN2 E have been
4 associated with normal content (allele effects of about 5 g of β -casein per litre), whereas the CSN2 0
5 and CSN2 01 alleles have been associated with non-detectable levels of β -casein. Most of these
6 alleles have been characterized genetically. Herein, we report the identification of a previously
7 unreported SNP in the goat CSN2 promoter region (AJ011018:g.1311T>C), which is associated with
8 the absence of β -casein in the milk. Furthermore, we developed a PCR-based method that allows
9 detection of this mutation.

10

11

12 **Keywords** β -casein, goat, null allele, promoter, SNP.

13

1 β -casein is the most abundant protein component (about 10 g/l) in goat milk (Grosclaude et al. 1987).
2 The goat b-casein (CSN2) gene maps to chromosome 6 and its organization is similar to that observed
3 in other species (Rijnkels 2002). To date, eight alleles identified at this locus are associated with two
4 expression levels: the CSN2A, CSN2A1, CSN2B, CSN2C, CSN2D and CSN2E alleles are associated
5 with normal content (Roberts et al. 1992; Mahe´ & Grosclaude 1993; Neveu et al. 2002; Galliano et
6 al. 2004; Cosenza et al. 2005; Caroli et al. 2006), whereas the CSN20 and CSN201 alleles are
7 associated with non-detectable amounts of this protein (Ramunno et al. 1995; Persuy et al. 1999).
8 Analysis of the coagulation properties of milk with and without b-casein demonstrates that milk
9 without b-casein shows longer coagulation times (about three times the normal value, 15–25 min vs.
10 4–7 min) and low curd firmness (so low that it is impossible to measure). Furthermore, cheese yield
11 (caciotta at 30 days ageing) from milk without b-casein is about 80% of that obtained from milk with
12 a normal content of this casein fraction (Chianese et al. 1993). With the exception of the CSN2B
13 allele, the DNA and protein sequences of these alleles are known (Roberts et al. 1992; Mahe´ &
14 Grosclaude 1993; Ramunno et al. 1995; Persuy et al. 1999; Neveu et al. 2002; Galliano et al. 2004;
15 Cosenza et al. 2005; Caroli et al. 2006). The CSN201 allele is characterized by a single-nucleotide
16 substitution at position 373 of the seventh exon (Ramunno et al. 1995) (AJ011018:g.8915C>T), while
17 the CSN20 has a single nucleotide deletion (adenine) in a row of four adenines between nucleotide
18 16 and 19 of exon 7 (Persuy et al. 1999) (AJ011018:g.8561delA). These mutations result in a
19 truncated protein at amino acids 57 (Persuy et al. 1999) (p.Ile49SerfsX10) and 181 (Ramunno et al.
20 1995) (p.Gln182X) respectively.
21 Levels of mRNA product transcribed by the CSN20 and CSN201 alleles are about 100 (Persuy et al.
22 1999) and 10 (Ramunno et al. 1995) times lower than normal expression respectively. More recently,
23 Cunsolo et al. (2005) reported on the identification and characterization of a truncated b-casein in the
24 milk of goats homozygous for the CSN201 allele. The truncated protein contained 1–166 amino acid
25 residues of the mature b-casein variant A. So far, research on the polymorphisms associated with
26 differences in the expression of b-casein has been mainly limited to exonic regions of CSN2.

1 However, mutations in the promoter region might be responsible for differences in the level of gene
2 expression by modifying either the level of transcription or the mRNA stability and, consequently,
3 the content of a particular protein in the milk (Martin et al. 2002; Prinzenberg et al. 2003;
4 Szymanowska et al. 2004; Kuss et al. 2005). Moreover, it has been suggested that differential
5 expression of various milk-protein alleles is a possible result of linkage between variants of coding
6 and regulatory regions of their genes (van Eenennaam & Medrano 1991; Ramunno et al. 2005).
7 Therefore, the objective of this study was to examine associations between polymorphisms in the 5'-
8 flanking region of the goat CSN2 gene and the b-casein content in the milk.

9 Comparisons between sequences of goat CSN2A (AJ011018) and CSN201 (AJ011019) alleles
10 showed two transitions located in the 5' gene-flanking region: g.1538A>G, which was already
11 reported by Pappalardo et al. (1997), and g.1311T>C. Because nucleotides T in position 1311 and A
12 in position 1538 have been found not only in *Capra hircus* promoter sequences (DQ673920,
13 DQ673919, AY834229, AY398686, M90559, AY311384) but also in other ruminant species such as
14 *Ovis aries* (X79703), *Bubalus bubalis* (AY352050), *Bos taurus* (AJ973327, U47012, M55158,
15 U47013, X14711, M75888) and *Bos grunniens* (AF194986), these sequences might represent the
16 ancestral state of the gene.

17 To assess the effect of these two mutations in the promoter region on b-casein level in goat milk, we
18 analysed the genomic DNA of 854 goats in five breeds: 74 Garganica, 115 Malta, 90 Alpine, 95
19 Saanen and 480 Southern Italy population of undefined genetic type. Genomic DNA was extracted
20 from leucocytes (Goossens & Kan 1981) obtained from blood samples collected using Na₂EDTA as
21 anticoagulant.

22 Milk from the same individuals was previously analysed by SDS-PAGE according to Grosclaude et
23 al. (1987). Moreover, each DNA sample was genotyped for the presence of the mutation g.8915C>T
24 by allele-specific amplification (AS-PCR) (Ramunno et al. 1995). Genotyping for the transition
25 g.1538A>G was performed by MseI PCRRFLP (Pappalardo et al. 1997) and an AS-PCR was set up
26 for the transition g.1311T>C. Sequence primers used for the AS-PCR for the transition g.1311T>C

(184 bp in length) and amplification conditions are listed in Table S1. Primers for the amplification of goat CSN2 exon 9 were also included in the PCR reactions as a positive control (360 bp in length). Amplifications were performed in a 50- μ l volume containing from 100 to 200 ng of genomic DNA, 1x PCR Buffer, 1.5 mM MgCl₂, 200 μ M of each dNTP, 0.04% BSA, 10 pmol of each primer, 2.5 U Taq DNA polymerase (Promega). Amplified fragments were analysed by means of electrophoresis in 2% agarose gels stained with ethidium bromide. In the present study, the lack of b-casein in the milk was always in cis with the g.1538G allele, but this allele has been associated with normal b-casein levels in other studies. Therefore, this mutation is believed not to be involved in the lack of expression of CSN2. On the contrary, all goats whose milk produced an SDS-PAGE pattern apparently without the b-casein fraction (Fig. 1, lane 1) (15 Southern Italy and three Malta samples) and those goats with a band less intense than normal (about 50%, Fig. 1, lane 2) (11 Garganica, 15 Malta and 81 Southern Italy animals) were homozygous or heterozygous respectively for the g.1311C and g.8915T alleles (Table 1). All samples that produced a normal SDS-PAGE pattern (Fig. 1, lane 3) (63 Garganica, 97 Malta, 90 Alpine, 95 Saanen, 384 Southern Italy samples) were homozygous for the g.1311T and g.8915C alleles (Table 1). The frequencies of the g.1311C and g.8915T alleles were 0.074, 0.091 and 0.115 for the Garganica and Malta breeds and Southern Italy population respectively. The overall frequencies of g.1311C and g.1538G were 0.084 and 0.152 respectively. Sequence analyses of the CSN2 promoter region based on TRANSFAC 7.0 database (<http://www.gene-regulation.com/pub/databases.html>) indicate that the presence of g.1311C does not alter or create any regulatory sites (Fig. 2). However, given the absence of the b-casein in animals with this allele, it is possible that this mutation is involved in gene regulation processes. It is also possible this allele is in linkage disequilibrium with a causative mutation for lack of expression. Sequencing of the complete genomic sequence of the CSN2 gene in these animals is needed.
